

Wikipedia task (N = 101): pre-registered analysis null, writing-pattern entropy shows a robust signal

Pre-registered analysis

PC1 of three switch counts (time, topic, typing)

d = +0.04, p = 0.83

no condition difference

Exploratory finding

Writing entropy across pages

d = +0.69, p = 0.001

Diffuse > Clumpy

The manipulation does not move the pre-registered switch counts,
but it does change HOW writing is distributed across pages:
Diffuse integrates writing throughout the search; Clumpy accumulates it into long streaks.

The 5 writing-pattern measures, plus two robustness checks

(A) defines the measures used throughout. (B) and (C) re-analyze them from different angles.

(A) The 5 writing-pattern measures

used throughout panels B and C

What they capture: each measure captures the W/N sequence from a different angle.

Writing entropy	- balance between W and N pages across the question
Longest write/no-write streak	- longest run of a single label (W or N)
Time to first writing (s)	- latency until the first writing on any page
Mean reading-only streak	- average length of consecutive no-write (N) pages
Mean same-topic streak	- average length of consecutive pages on the same LDA topic

(B) Does the effect survive controlling for output volume?

YES - it strengthens

What the bars show: effect size for each measure, before vs after partialling out final answer length in a regression.

(C) Does the effect decay or grow across questions?

GROWS on Q2

What the bars show: effect size on participants' first vs second question (question order was randomised across participants).
