

OLD vs NEW: does the Diffuse-vs-Clumpy effect strengthen?

N_old = 101 N_new = 138

Measure	d OLD	d NEW	$\Delta d $	Verdict
Mean reading-only	-0.32	-0.13	-0.19	weakened
Switch count: time	-0.01	-0.04	+0.02	unchanged
Switch count: topic	-0.08	-0.10	+0.02	unchanged
Switch count: typin	+0.16	-0.06	-0.10	weakened
PC1 (composite)	-0.04	-0.09	+0.05	unchanged

d = signed Cohen's *d* for Diffuse - Clumpy (negative = clumpy higher). Verdict based on $|d|$: strengthened if $|d|$ grew by ≥ 0.05 , weakened if it dropped by ≥ 0.05 .

OLD sample (N = 101): pre-registered analysis null, reading-only streaks show a robust signal

Pre-registered analysis

PC1 of three switch counts (time, topic, typing)

d = -0.04, p = 0.83

no condition difference

Exploratory finding

Mean reading-only streak

d = -0.32, p = 0.122

Clumpy > Diffuse

The manipulation does not move the pre-registered switch counts,
but it does change HOW writing is distributed across pages:

In Clumpy, the average reading-only stretch is longer - writing concentrates into bursts with longer non-writing gaps.

In Diffuse, writing is interleaved throughout the search, keeping reading-only stretches short.

NEW sample (N = 138): pre-registered analysis null, reading-only streaks show a robust signal

Pre-registered analysis

PC1 of three switch counts (time, topic, typing)

d = -0.09, p = 0.60

no condition difference

Exploratory finding

Mean reading-only streak

d = -0.13, p = 0.448

Clumpy > Diffuse
